Crop Recommendation System using Machine Learning

Abhinav Singh (S24CSEU1759)
Kashish Kapoor (S24CSEU1764)

1. Introduction

Agriculture plays a very important role in the economy of many countries, especially in developing nations. Farmers often face difficulties in selecting the most suitable crop for their land because crop productivity depends on several factors such as soil nutrients, temperature, rainfall, and soil pH. Traditionally, farmers rely on their experience or advice from local experts to decide which crop to grow. However, this approach may not always provide accurate results, especially when environmental conditions change.

With the advancement of technology, machine learning techniques can help in making better agricultural decisions. Machine learning allows computers to analyze historical agricultural data and identify patterns that help in predicting suitable crops for specific soil and climate conditions.

The proposed project focuses on developing a **Crop Recommendation System using Machine Learning**. The system will analyze different environmental and soil parameters and recommend the most suitable crop that can be cultivated under those conditions.

The model will be trained using a dataset containing information about soil nutrients and environmental factors. Based on these inputs, the system will predict the best crop that a farmer should grow. A simple user interface will also be developed so that users can easily input the required values and obtain crop recommendations.

The purpose of this project is to demonstrate how machine learning techniques can be applied in agriculture to assist farmers in making better decisions and improving crop productivity.

---

2. Problem Definition

Selecting the correct crop for a particular piece of land is a challenging task. The growth and productivity of crops depend on multiple factors such as soil nutrients, temperature, humidity, rainfall, and soil pH. If farmers choose crops that are not suitable for the given soil and environmental conditions, it may lead to poor yield and financial losses.

Many farmers do not have access to scientific tools that help them analyze these factors and make informed decisions. As a result, they often rely on traditional methods or guesswork, which may not always produce optimal results.

The problem addressed in this project is the lack of an intelligent system that can assist farmers in choosing the most appropriate crop based on soil and environmental conditions.

The proposed system aims to solve this problem by developing a machine learning model that can analyze agricultural data and recommend the most suitable crop. The system will take important parameters such as nitrogen, phosphorus, potassium levels, temperature, humidity, soil pH, and rainfall as input and will predict the most appropriate crop.

This system can help improve agricultural decision-making and provide farmers with a simple tool to determine suitable crops for their land.

---

3. Objectives of the Project

The main objective of this project is to design and develop a machine learning based system that can recommend suitable crops based on soil and environmental parameters.

The specific objectives of the project are as follows:

1. To study how machine learning techniques can be applied in agriculture for crop recommendation.
2. To collect and analyze agricultural datasets containing information about soil nutrients and environmental conditions.
3. To preprocess and prepare the dataset for machine learning model training.
4. To build a crop prediction model using the Random Forest algorithm.
5. To compare the performance of the Random Forest model with other machine learning algorithms such as Decision Tree, K-Nearest Neighbors, and Naive Bayes.
6. To evaluate the accuracy and performance of different machine learning models.
7. To develop a simple graphical user interface using Streamlit that allows users to enter input parameters and obtain crop recommendations.
8. To demonstrate how machine learning can support agricultural decision making.

---

4. Literature Review

Several researchers have explored the use of machine learning and deep learning techniques for crop recommendation and agricultural decision support systems. Early studies focused on traditional machine learning algorithms such as Decision Trees, Naive Bayes, and K-Nearest Neighbors to analyze soil and environmental parameters for predicting suitable crops.

Pudumalar et al. developed a crop recommendation system using Decision Tree and Naive Bayes algorithms based on soil nutrients and climatic conditions. Their results showed that machine learning techniques can effectively recommend crops using parameters such as nitrogen, phosphorus, potassium, temperature, humidity, and rainfall.

Rajak et al. and Doshi et al. further improved crop recommendation systems by applying ensemble learning methods and neural networks. These studies showed that algorithms such as Random Forest and Artificial Neural Networks can significantly improve prediction accuracy compared to traditional approaches.

More recent research has explored advanced machine learning and deep learning models. For example, Dey et al. applied multiple machine learning models including Support Vector Machine, XGBoost, Random Forest, and K-Nearest Neighbors to agricultural datasets containing soil nutrient and climate variables. Their experiments demonstrated improved prediction performance for crop recommendation tasks.

Similarly, Shastri et al. proposed a Gradient Boosting model that achieved very high accuracy in crop recommendation tasks. In addition, deep learning based approaches such as Deep Neural Networks and Bi-LSTM networks have also been investigated for agricultural prediction problems. These models can capture complex relationships between environmental parameters and crop suitability but often require large datasets and higher computational resources.

Overall, previous research demonstrates that machine learning and deep learning techniques can significantly assist farmers in selecting suitable crops based on soil and climatic conditions. Among these methods, ensemble models such as Random Forest and Gradient Boosting have shown strong performance and reliability in crop recommendation systems. Therefore, the proposed project focuses on using Random Forest as the primary model and comparing its performance with other machine learning algorithms.

Ref	**Technique Used**	**Dataset Used**	**Performance**	**Limitations**
[1] Pudumalar et al. (2017)	Decision Tree and Naive Bayes	Soil nutrient dataset containing N, P, K, pH, temperature, humidity, rainfall	Accuracy ≈ 91%	Model performance decreases when dataset size increases
[2] Rajak et al. (2017)	Random Forest and KNN	Agricultural dataset with soil nutrients and climatic parameters	Accuracy ≈ 95%	Requires large training data to improve prediction
[3] Doshi et al. (2018)	Artificial Neural Network (ANN)	AgroConsultant agricultural dataset with rainfall and soil properties	Accuracy ≈ 91%	Neural networks require high computational resources
[4] Garanayak et al. (2021)	Regression-based ML models	Soil fertility dataset containing environmental and nutrient parameters	Accuracy ≈ 93%	Model accuracy depends strongly on weather conditions
[5] Gosai and Raval (2021)	SVM, Random Forest, Logistic Regression	Crop recommendation dataset with NPK, temperature, humidity, pH and rainfall	Accuracy ≈ 96%	High training time for large datasets
[6] Biplob Dey et al. (2024)	SVM, XGBoost, Random Forest, KNN	Agricultural dataset including NPK, soil pH and climatic variables	Accuracy ≈ 97%	Dataset limited to specific crop categories
[7] Shastri et al. (2025)	Gradient Boosting Model	Crop recommendation dataset with nutrient and climate parameters	Accuracy ≈ 99.27%	Risk of overfitting on smaller datasets
[8] Paithane et al. (2023)	Random Forest Classifier	Crop dataset including temperature, humidity, pH and rainfall	Accuracy ≈ 99%	Computational complexity increases with number of trees

Ref	Technique Used	Dataset Used	Performance	Limitations
[9] Islam et al. (2021)	Deep Neural Network (DNN)	Agricultural dataset with climate, soil and fertilizer parameters	Accuracy ≈ 94%	Requires large dataset for effective training

5. Methodology

The proposed crop recommendation system will follow several steps to build and evaluate the machine learning model.

5.1 Dataset Collection

The system will use an agricultural dataset containing information about soil nutrients and environmental factors. The dataset consists of approximately **2200 records** and contains the following input features:

- Nitrogen (N)
- Phosphorus (P)
- Potassium (K)
- Temperature
- Humidity
- Soil pH
- Rainfall

The target variable in the dataset is the **crop name**, which represents the most suitable crop for the given conditions.

The dataset contains multiple crop categories such as rice, maize, wheat, cotton, mango, banana, and others.

5.2 Data Preprocessing

Before training the machine learning model, the dataset will be preprocessed. This step includes:

- Handling missing values if present
- Checking data distribution

- Visualizing data relationships using graphs
- Splitting the dataset into training and testing sets

Data preprocessing will be performed using libraries such as Pandas and NumPy.

5.3 Model Training

The primary machine learning algorithm used in this project will be the **Random Forest classifier**. Random Forest is an ensemble learning algorithm that builds multiple decision trees and combines their predictions to produce a more accurate result.

The model will be trained using the training portion of the dataset.

5.4 Model Comparison

In order to evaluate the effectiveness of the Random Forest model, its performance will also be compared with other machine learning algorithms such as:

- Decision Tree
- K-Nearest Neighbors (KNN)
- Naive Bayes

The accuracy of each model will be calculated to determine which algorithm performs best for crop prediction.

5.5 Model Evaluation

The models will be evaluated using performance metrics such as:

- Accuracy score
- Confusion matrix
- Classification report

Visualization tools such as Matplotlib and Seaborn will be used to display model performance and data insights.

5.6 User Interface Development

To demonstrate the working of the system, a simple graphical interface will be developed using Streamlit.

The interface will allow users to input values such as:

- Nitrogen

- Phosphorus
- Potassium
- Temperature
- Humidity
- Soil pH
- Rainfall

After entering the required values, the system will process the input through the trained machine learning model and display the recommended crop.

This interface will make the system easy to use and help demonstrate the practical application of the machine learning model.
